EchoPress 20-Minute Demo Presentation Script

Host-led version for a Microsoft Teams presentation.

Presenter Setup

- Use separate browser profiles, separate browsers, or incognito windows for each role. Do not use five normal tabs in one browser profile, because the app stores authentication tokens in browser storage and the sessions will overwrite each other.
- Prepare these windows before the meeting:
    - Slide deck or title slide
    - Student
    - Coordinator
    - Manager
    - Guest
    - Admin
    - Backup screenshots folder
- Verify the live demo credentials before the meeting. The workspace documents contain inconsistent sample credentials, so confirm which seeded accounts are actually active on the deployed or demo environment.
- Prepare demo data in advance:
    - at least one Submitted contribution
    - at least one Under Review or Approved contribution
    - at least one Selected contribution
    - at least one guest account linked to a faculty
    - one active contribution window
- If your tutor expects visible contribution from multiple team members, keep short handover points ready after the Agile section, after the Student or Coordinator section, and before the closing summary. You can still remain the main host while letting others speak for 20 to 40 seconds each.

- Keep one valid .docx file and one image ready on the desktop in case you want to show the upload step.
- Set browser zoom to around 110% to 125% for readability during screen share.
- Disable desktop notifications and Teams pop-ups before sharing.

Delivery Goal

Your main message is:

"EchoPress is not just a set of screens. It is a secure, role-based, faculty-scoped workflow system that translates the coursework brief into a working end-to-end product."

Keep repeating these ideas naturally throughout the talk:

- secure role-based access
- faculty-scoped data isolation
- dual-deadline contribution workflow
- 14-day coordinator review rule
- statistical and exception reporting
- responsive design across devices
- agile team delivery with evidence

20-Minute Script

0:00-1:20 | Opening

Screen: Title slide with project name, module, and group name.

Say:

"Good [morning/afternoon], and thank you for your time. We are Group B1, and today we are presenting EchoPress, our coursework product for COMP1640 Enterprise Web Software Development.

EchoPress is our digital contribution management system for the university magazine. We built it to solve the problems of a manual submission process, where contributions are difficult to collect, review, monitor, and prepare for publication in a controlled way.

Our system supports a complete journey. Students create and submit contributions. Coordinators review and comment within a faculty-scoped workflow. Managers monitor

selected work and prepare exports. Guests browse the selected archive in read-only mode. Administrators manage users, roles, deadlines, and system monitoring.

In the next twenty minutes, I will show how the system works, how it satisfies the core coursework and Version 2 requirements, and why our team delivered it as one coherent product rather than a collection of separate pages."

1:20-2:40 | Coursework Scope And Business Problem

Screen: Slide with the five roles and the main workflow.

Say:

"The business problem in the brief is larger than simple upload functionality. The university needs a controlled publishing pipeline. That means five different roles, faculty-based access restrictions, Word and image submission, mandatory terms and conditions, submission and closure deadlines, coordinator comments within 14 days, ZIP export of selected contributions, guest viewing, administrative governance, and analytical reporting.

Our design goal was to convert those written rules into visible workflows. In other words, not just to store data in the database, but to make the rules understandable and actionable through the interface."

2:40-4:00 | Agile Delivery And Team Contribution

Screen: Slide with sprint summary, Jira artefacts, burndown charts, and team roles.

Say:

"We developed EchoPress through five sprints using agile Scrum practices. We documented backlog items, sprint planning, meeting minutes, burndown charts, user flows, wireframes, testing artefacts, and role responsibilities.

Our sprint sequence was deliberate. We built security and routing first, then student submission, then coordinator review, then reporting and administration, and finally guest access, export, testing, and polish. That sequencing reduced integration risk and helped us deliver visible business value in each sprint.

As a team, we combined frontend, backend, database, testing, UI, and documentation work, so the final submission reflects coordinated delivery rather than isolated tasks."

4:00-5:10 | Architecture And Technology Choices

Screen: Architecture slide.

Say:

"Technically, the frontend is built with React, TypeScript, Vite, TanStack Router, TanStack Query, Tailwind CSS, and chart components for analytics.

The backend is an ASP.NET Core Web API following a clean architecture with separate API, Application, Domain, and Infrastructure layers. PostgreSQL stores the operational data and also supports reporting views. Security uses JWT-based authentication, role and permission checks, faculty-scoped authorization, and Argon2id password hashing.

This matters because our coursework is not only about interface design. It is also about security, maintainability, data integrity, and quality of implementation across the full stack."

5:10-6:20 | Login, Security, And Version 2 Requirement 1

Screen: Login page, then sign in as Admin.

Action:

- Log in.
- If the first-login welcome modal appears, show it briefly.
- If it does not appear, open the user menu and show the last login date and time.

Say:

"I will begin with authentication and security. Users sign in with role-based accounts, and the system redirects them to the correct dashboard for their role.

Version 2 required the system to remind users of their last login date and time. We satisfy that in the user profile menu, and for first-time logins we also display a welcome modal. So security awareness is not hidden in the backend only; it is surfaced in the interface.

On top of that, route guards in the frontend and authorization rules in the backend work together, which means access control is enforced across both layers."

6:20-8:40 | Student Journey

Screen: Student dashboard.

Action:

- Switch to the student window.
- Show the dashboard, deadline banner, stat cards, and active contribution window.

- Open New Contribution.
- Walk through the three-step modal.
- Show the draft and submit options.
- Open My Contributions.
- Open one prepared contribution detail panel.

Say:

"Now I will move to the student journey, which is the core content-entry flow in the system.

The dashboard immediately shows contribution status cards and the active contribution window. This supports the coursework rule that students need to understand both their own progress and the submission deadlines. You can see the dual-deadline model clearly here: the submission end date stops new entries, while the final closure date controls how long updates are still allowed.

A student begins by creating a new contribution.

Creating a new contribution is guided through three structured steps. First, the student must accept the Terms and Conditions, which is a direct coursework requirement. Second, they enter the article details, including title, description, and category. Third, they upload the required Word document and, optionally, an image. The form validates file type and size before the contribution can move forward.

At this point, they have two possible paths: they can save the work as a draft or submit it directly to the coordinator of their faculty.

When saved as a draft, the student retains full control. They can return later to refine the content, update details, or delete the draft entirely if they decide not to continue.

If the student chooses to submit, the contribution immediately moves forward in the workflow. It is sent directly to the coordinator, who then reviews it for quality and relevance. From that point, the student moves from content creation into tracked workflow participation.

For demonstration purposes, we show the validated form and then the resulting lifecycle using prepared data. In the My Contributions area, the student can track the status of the work across multiple stages: draft, submitted, under review, revision required, approved, selected, or rejected. Opening a contribution reveals a detail panel with the status timeline, uploaded files, rating display, and comment history. That gives the student a clear, traceable view of what happened to the submission at each stage of the process."

8:40-11:10 | Coordinator Journey And 14-Day Review Rule

Screen: Coordinator dashboard, review queue, contribution detail panel, analytics page, guest list page.

Action:

- Switch to Coordinator.
- Pause on the dashboard and show the compliance banner, workload cards, and the Go to Review Queue action.
- Open Review Queue.
- Use the status filters or deadline chips to show how the coordinator focuses on submitted, urgent, or overdue work.
- Open one prepared Submitted contribution and show the detail panel.
- Show the attached files and the comment area. If safe, add one short comment.
- If safe, click Start Review to move the item into Under Review.
- Mention that once an item is under review, the coordinator can rate it and choose Approve, Request Revision, or Reject.
- If you have a prepared approved item, briefly show that Select for Magazine appears after approval.
- Briefly open Coordinator Analytics.
- Briefly open Guest List.

Say:

"Now I will present the coordinator role. This is the operational review role in our system, and it is faculty-scoped, so the coordinator only sees submissions and guests from their own faculty.

I start on the coordinator dashboard. This page gives an immediate overview of current submissions, review status, and compliance with the 14-day comment rule. The banner at the top turns that rule into something actionable by showing overdue, urgent, and on-track items rather than hiding the deadline logic in the backend.

Below that, the status cards let the coordinator jump directly to submitted, under review, revision required, approved, selected, or rejected items. This helps the coordinator move quickly from summary into the actual review workload.

When the Request Review button is clicked, the contribution moves to the Revision status. At this stage, the student is allowed to edit their contribution and resubmit it after making the necessary changes.

On the other hand, when the Reject button is clicked, the contribution is moved to the Rejected status. In this case, the student can no longer edit or resubmit the contribution.

Next, I open the review queue. Here the coordinator can search, filter by status, switch between grid and list views, and focus specifically on urgent or overdue submissions. This is important because the coordinator is not just reading data; they are managing a live review pipeline.

When I open one contribution, the detail panel shows the subject, description, category, uploaded files, rating area, 14-day comment indicator, and full comment history. The coordinator can download the files for offline checking, add feedback comments, and take workflow actions based on the current status.

click to open downloaded zip, no need extract

For a newly submitted contribution, the first action is Start Review. Once the item is under review, the coordinator can set a rating and then decide whether to approve it, request revision, or reject it. If a contribution has already been approved, a further action becomes available: Select for Magazine. That keeps the workflow explicit and traceable.

Coordinator instantly choose to select for magazine as well as under Approved status filter after the decision to select.

After the live review view, I briefly move to Coordinator Analytics. This page turns the coordinator's work into management information by showing status distribution, 14-day compliance, approval rate, and an exception report for pending or overdue comments.

Finally, I open the Guest List page. Version 2 required coordinators to see the guests registered within their faculty, and this page supports that with searchable guest records.

In summary, the coordinator role is responsible for review quality, student feedback, compliance with the 14-day rule, and final publication selection within a faculty-scoped workflow."

11:10-13:10 | Manager Journey, Statistical Reports, And ZIP Export

Screen: Manager dashboard, then export center.

Action:

- Switch to Manager.
- Pause on the dashboard header and point out the direct Export Center action.
- Show the KPI cards first.
- Move down to Executive Overview.
- Demonstrate the academic-year filter in Faculty Performance Analysis.
- Briefly point out the faculty charts, Comment Tracking Reports, and Top Contributors.
- Open Export Center.
- Show the summary cards, then demonstrate Select All, faculty group selection, and an individual contribution checkbox.

- Point to the bulk Download button and the single-item download action.

Say:

"Now I will present the manager role. The manager role is designed for publication oversight and export preparation. Unlike the student role, which creates content, or the coordinator role, which reviews content, the manager role focuses on understanding selected contributions at a high level and preparing them for export.

This role is intentionally simple. The manager has two main pages: the dashboard and the export center. That keeps the workflow focused on monitoring publication-ready content and preparing final outputs for download.

I start on the Manager Dashboard. This page gives a high-level overview of selected contributions across all faculties. Its purpose is not editing or reviewing. Its job is to help the manager understand publication readiness, faculty performance, contributor activity, and export-related risk.

At the top, we show the page title, a short description, and a direct action button to the Export Center because export is the main operational action for this role.

The KPI cards summarize the most important publication numbers: total selected contributions, selected publications and selection rate, active faculties, and student contributors. These KPIs help the manager understand the publication landscape quickly before reading detailed tables.

Next, the Executive Overview gives broader management insights such as total student contributors, average contributions per faculty, contribution yield, and the review watchlist. This is useful because it connects publication output with contributor activity and process health.

The dashboard also supports academic-year filtering. That is important because reporting often needs a time scope. The manager may want to review all data or focus on a specific academic year for comparison.

In the faculty performance area, the manager can compare contribution volume, contributor participation, and percentage share by faculty. The small charts make the dashboard easier to scan because the manager can compare faculties visually instead of relying only on raw numbers.

We also show Top Contributors and Comment Tracking Reports. These sections highlight strong contributors and surface operational risks such as submitted contributions without comments and items that have passed the 14-day comment window.

Now I move to the Export Center. This is the manager's main operational page. At the top, the back button returns to the dashboard, and the summary cards show the number of selected contributions, the number of faculties in export, and how many items are currently selected.

The export list is grouped by faculty. The manager can select everything at once, select one whole faculty group, or select individual contributions. Once items are selected, the manager can use the bulk download button to export them together as a ZIP package. If needed, a single contribution can also be downloaded individually.

So overall, the design separates overview from action: the dashboard explains the publication situation, and the export center performs the final manager task. This keeps the manager workflow clear, efficient, and read-only."

Note for live delivery: If the ZIP download triggers a save dialog that interrupts the demo, stop at the selection screen and say, "At this point the manager can export the selected items as a ZIP archive." Do not wait for the download dialog on screen.

13:10-14:20 | Guest Journey

Screen: Guest dashboard and selected contributions archive.

Action:

- Switch to Guest.
- Pause on the dashboard hero area and badges.
- Show the summary cards and the two main actions: Browse archive and Open latest highlight if it appears.
- Briefly point out that the page is built for archive discovery, not workflow actions.
- Open Selected Contributions.
- Show the archive header, search box, year filter, sort control, and grid/list toggle.
- Open one selected contribution to show the read-only detail panel.

Say:

"Now I will present the guest role. This role is intentionally simple and read-only. Guests can explore selected contributions from their faculty, but they cannot create, edit, comment, approve, or change workflow state.

That is the selling point of this role: it gives visibility without losing control.

The Guest Dashboard is designed as an archive-first landing page. It immediately tells the guest what is available through summary cards, highlights selected content, and gives a direct path into the archive.

When I open Selected Contributions, this becomes the main discovery page. Guests can search by title, description, or contributor, filter by year, change the sort order, and switch between grid and list views. So the archive is not just visible; it is easy to browse.

If I open one contribution, the detail panel shows the content, attached files, rating display, and comment history. But the experience stays read-only, which keeps external access safe and controlled.

So in one sentence, the guest journey delivers secure archive exploration: clear overview, easy discovery, and controlled read-only access to selected work."

14:20-16:30 | Administrator Governance And Version 2 Monitoring

Screen: Admin contribution windows, user management, faculty management, role management, then system monitoring.

Action:

- Switch to Admin.
- Show Contribution Window Management.
- Quickly show User Management, Faculty Management, and Role Management.
- Open System Monitoring.

Say:

"The administrator governs the system data that all other workflows depend on.

In contribution window management, the admin defines academic years, submission open dates, submission end dates, and final closure dates. This is how we enforce the dual-deadline model from the brief.

The admin also manages users, faculties, and roles. In our current coursework design, the five main user-facing areas are built around the coursework roles, while this admin area manages the governance data behind them.

Version 2 added platform monitoring, and this is where that is implemented. In the overview tab, the admin can see the most viewed pages, browser usage, and device usage. In analytics,

the admin can inspect hourly activity, most active users, and faculty user distribution. In summary, the admin gets a concise system-wide picture of platform usage.

This is valuable because it shows the project is not only about content submission. It also considers operational visibility and system stewardship."

16:30-17:30 | Responsive Design

Screen: Any dashboard, ideally Student or Manager.

Action:

- Resize the browser from desktop to tablet width and then to mobile width.

Say:

"The brief also required the interface to work across mobile, tablet, and desktop. We designed responsiveness into the layout early rather than treating it as final decoration.

As I resize the screen, you can see the sidebar collapse, cards reflow, tables adapt, and the content remain readable. This is especially important in a multi-role system, because usability has to stay consistent even when each role has different screens and priorities."

17:30-18:40 | Testing, Quality, And Notification Features

Screen: Testing summary slide or backup artefact slide.

Say:

"Beyond the live demo, we also carried out structured testing to make sure the system works correctly and delivers a reliable user experience.

We tested all major roles in the workflow, including admin, student, coordinator, manager, and guest. We also tested responsive behaviour across desktop, tablet, and mobile layouts, because the coursework required the platform to remain usable across devices.

For quality assurance, we prepared structured test cases, execution logs, and recorded outcomes. In total, we designed 66 test cases, and the results show that the system is stable with only minor issues remaining.

Alongside testing, we supported the development process with project artefacts such as wireframes, user flow diagrams, state diagrams, Jira backlog items, sprint records, and burndown charts. These helped us plan, track, and refine the product throughout delivery.

We also implemented email notifications for key events. For example, the system can notify coordinators when a student submits a contribution, and it can notify users when a guest account is created.

So the product does not only update information on screen. It also supports real communication, quality assurance, and evidence-based delivery, which strengthens the overall reliability and professionalism of the system."

18:40-20:00 | Strong Close

Screen: Closing slide with key achievements.

Say:

"To conclude, EchoPress is a secure, role-based, faculty-scoped platform that translates the coursework brief into a working end-to-end system.

It supports student contribution submission, coordinator review with 14-day monitoring, manager oversight and export, guest read-only access, administrator governance, Version 2 security reminders, and system monitoring. It is responsive across devices, supported by reporting, and backed by agile process evidence and testing artefacts.

What we believe makes this a strong submission is not only that the features exist, but that the workflow, security, reporting, and usability all work together as one coherent product.

Thank you very much. We are happy to take your questions."

Accuracy Guardrails

Use these exact truths during the presentation:

- Say the system tracks and exposes overdue coordinator review cases.
- Say email notifications are implemented for contribution submission and guest creation.
- Say the manager has read-only oversight and ZIP export capability.
- Say the admin manages contribution windows, users, faculties, roles, and monitoring.
- Say the interface is responsive across mobile, tablet, and desktop.

Avoid overclaiming these points:

- Do not say the system sends automated reminder emails for overdue 14-day comments unless you are personally certain your current deployment does that.
- Do not say the manager edits contributions. The manager role is read-only plus export.

- Do not say role management creates brand-new user-facing dashboard areas dynamically. The coursework roles still define the main application areas.
- Do not say the export is blocked before final closure unless you have verified that behaviour in your live environment.

Teams Delivery Tips

- Narrate before clicking, not after clicking. This makes the flow feel controlled.
- Pause for one second on each important screen so the tutor can absorb what is visible.
- If a page loads slowly, use the delay to explain why that screen matters to the coursework.
- If live data is not ideal, say: "We prepared representative records in advance so we can focus on the complete workflow rather than waiting for data entry."
- If the first-login modal does not appear, show the last-login reminder in the user menu instead.
- If a live action feels risky, explain the capability and move on. Smooth delivery is better than forcing every click.
